DEEP LEARNING APPROACHES FOR REAL-TIME AND SCALABLE SIGN LANGUAGE RECOGNITION SYSTEMS

ABSTRACT

Sign language serves as an essential means of communication for individuals with hearing and speech disabilities, allowing them to convey their ideas and emotions through specific hand gestures and movements. Despite its importance, its application remains limited due to the general lack of awareness and understanding across diverse societal settings. This project aims to create an adaptable system that utilizes Convolutional Neural Networks (CNNs) to identify and interpret sign language gestures. By focusing on gestures representing letters (A–Z) and numbers (0–9), the system employs deep learning techniques to automatically analyze and learn from visual gesture data. Training on a well-organized dataset resulted in impressive accuracy levels 96% for the training phase and 94% during validation—highlighting its potential. This innovative solution offers an efficient and automated method to reduce communication barriers and foster inclusion for individuals with hearing impairments in broader social interactions.

1. INTRODUCTION

Communication plays a crucial role in human interaction. For those with hearing and speech disabilities, sign language serves as their main mode of communication. By using hand gestures, facial expressions, and body movements, they can express their thoughts and emotions. However, the limited understanding of sign language among the general population and the absence of a universal standard creates significant barriers. This gap restricts effective communication between the hearing-impaired community and society at large.

Progress in artificial intelligence (AI) and machine learning has opened new avenues for developing innovative solutions to tackle these challenges. Convolutional Neural Networks (CNNs), a specialized deep learning technique, excel at analyzing visual data such as images. This project leverages CNNs to recognize sign language gestures, enabling the classification of alphabets and numbers with high accuracy. This report details the dataset, preprocessing steps, CNN architecture, training process, results, and challenges encountered, providing a comprehensive guide to implementing a sign language recognition system.

2. LITERATURE SURVEY

Research in sign language recognition has evolved significantly with the integration of machine learning and deep learning techniques.

2.1 TRADITIONAL METHODS

Earlier approaches relied on classical machine learning techniques like k-Nearest Neighbors (k-NN) & Support Vector Machines (SVMs), where features such as edges and shapes were manually extracted from images. While effective for small-scale datasets, these methods struggled with accuracy and scalability in real-world scenarios (Viswanathan et al., 2023).

2.2 ADOPTION OF CNNS

Introduction of Convolutional Neural Networks (CNNs) addressed the limitations of manual feature extraction. CNNs automatically learn patterns directly from images, enabling higher accuracy and better generalization. For instance, developed a CNN-based system that significantly improved recognition performance compared to traditional models. Raut et al. (2023)

2.3. CHALLENGES AND IMPROVEMENTS

Despite these advancements, challenges persist, such as the need for larger datasets and handling gestures with subtle differences. Concepts like transfer learning & data augmentation have been employed to enhance model performance, but real-world situations e.g., varying lighting and hand orientations remain hurdles (Jim et al., 2024).

2.4 WHAT IS A CNN?

A Convolutional Neural Network (CNN) is a specialized type of deep learning model primarily designed to process and analyze visual data, such as images or video frames. Unlike traditional machine learning models that require manually defined features, CNNs entails automatically learning and extracting relevant features from images. This makes them particularly effective in areas like facial recognition, Object detection & image classification, where complex visual patterns need to be understood.(Viswanathan et al., 2023)

At a prominent level, CNNs consist of multiple layers.

Convolutional Layers: These layers apply filters (or kernels) that scan over the input image to detect various features, such as edges, textures, and shapes. Filters are small grids of numbers that "slide" over the image to extract local patterns.

- **Pooling Layers**: After convolutional layers, the pooling layers reduce the spatial dimensionality of feature maps. This makes the network more efficient by minimizing the computational load, while retaining the most key features.
- **Fully Connected Layers**: These layers process the extracted features and combine them to make final predictions, typically in the form of class probabilities.

Activation Functions:

- **ReLU (Rectified Linear Unit):** Introduces non-linear model, allowing the model to learn complex patterns.
- **Softmax:** Converts the final output into class probabilities.

3.1 DATASET OVERVIEW

The dataset used in this project consists of images representing hand gestures for thirty-six classes: ten numeric digits (0–9) and twenty-six alphabetic characters (A–Z). Each class contains training and validation samples, ensuring a balanced representation for effective model learning.

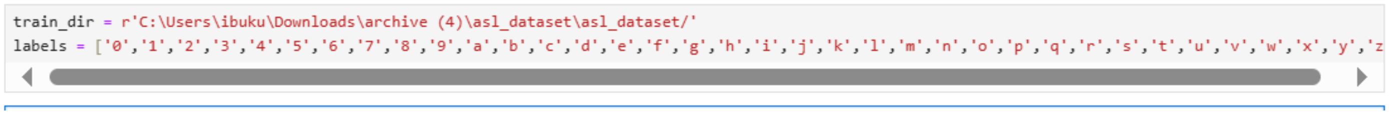
Key features of the dataset:

Classes: 36 (alphabets and numbers).

Training samples: sixty images per class.

Validation samples: ten images per class.

The images vary in resolution and orientation, requiring preprocessing to ensure uniformity and compatibility with the CNN model.



```
train_dir = r'C:\Users\ibuku\Downloads\archive (4)\asl_dataset\asl_dataset/'
labels = ['0','1','2','3','4','5','6','7','8','9','a','b','c','d','e','f','g','h','i','j','k','l','m','n','o','p','q','r','s','t','u','v','w','x','y','z
```

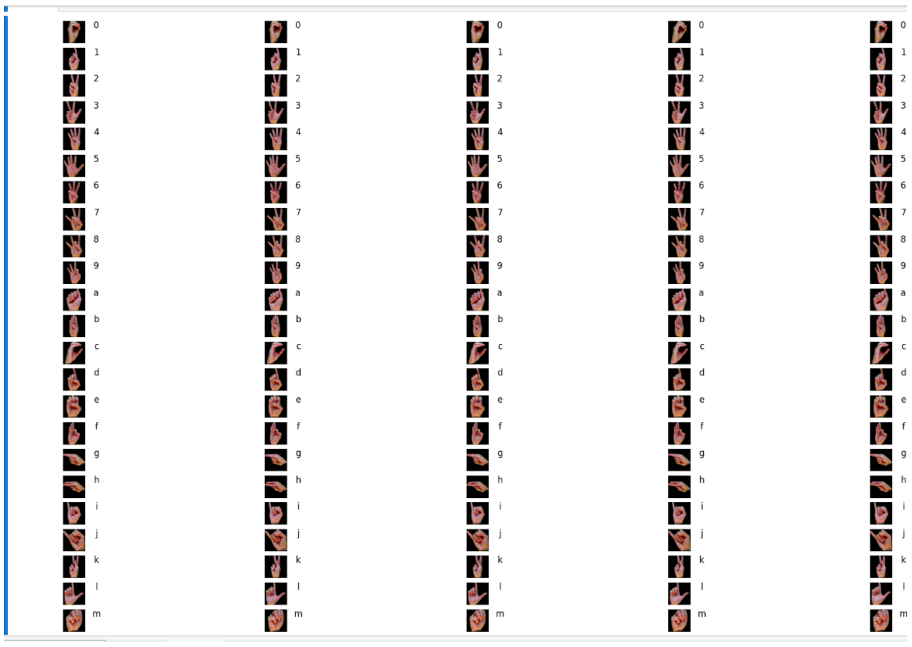


Figure 2: The labeled dataset (0-9, A-Z)

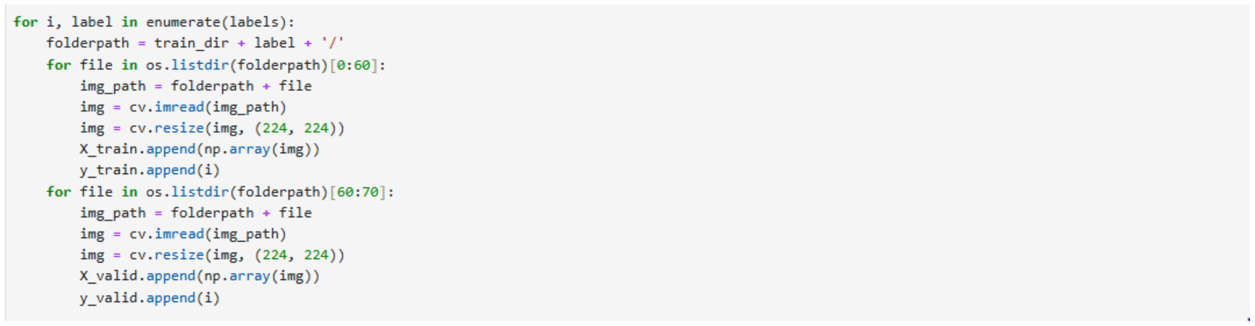
3.2 PREPROCESSING STEPS

To prepare the dataset for training, several preprocessing steps are applied to ensure that the images are consistent and suitable for feeding into the CNN:

- **Resizing**: Images are resized to 224x224 pixels to standardize their dimensions and make them suitable for processing by the CNN.
- **Normalization**: Pixel values, which by default ranges from 0 to 255, are then scaled to a range [0, 1] to improve the stability of the model during training.

- **Augmentation**: To enhance the dataset size and improve the model's generalization capabilities, image augmentation methods such as rotation, flipping, and zooming are utilized. These approaches introduce variations in gesture orientations, enabling the model to effectively identify gestures across diverse conditions.



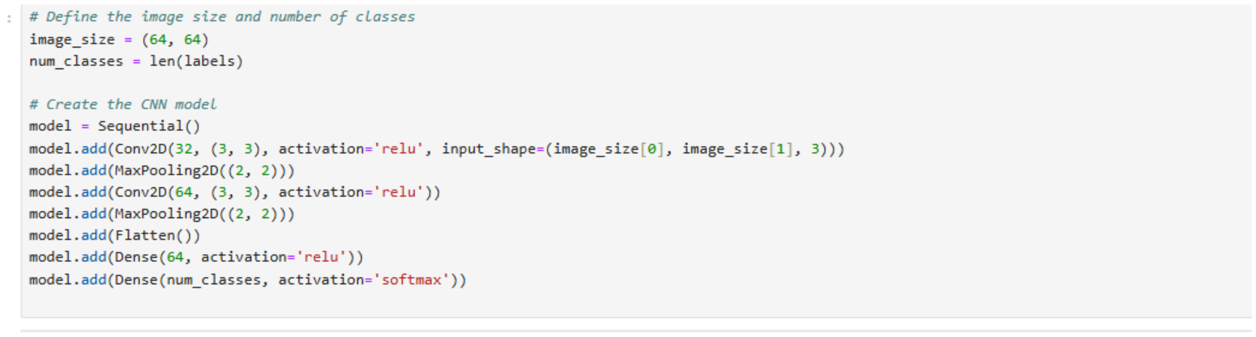
```
for i, label in enumerate(labels):
    folderpath = train_dir + label + '/'
    for file in os.listdir(folderpath)[0:60]:
        img_path = folderpath + file
        img = cv.imread(img_path)
        img = cv.resize(img, (224, 224))
        X_train.append(np.array(img))
        y_train.append(i)
    for file in os.listdir(folderpath)[60:70]:
        img_path = folderpath + file
        img = cv.imread(img_path)
        img = cv.resize(img, (224, 224))
        X_valid.append(np.array(img))
        y_valid.append(i)
```

Figure 3: Image preprocessing

4. CNN ARCHITECTURE

The CNN model for sign language recognition consists of the following layers:

a. **Input Layer:** Accepts images of size 224x224 with three color channels (RGB).
b. **Convolutional Layers**: Two convolutional layers' extract features using 32 and 64 filters, respectively, with three-by-three kernel sizes.
c. **Pooling Layers**: Max-pooling layers reduce spatial dimensions while retaining key features.
d. **Dropout Layer**: Introduces regularization by randomly deactivating 50% of the neurons to prevent overfitting.
e. **Fully Connected Layers:** A dense layer with 128 neurons, followed by a softmax output layer with 36 classes (26 alphabets + 10 digits).



```
# Define the image size and number of classes
image_size = (64, 64)
num_classes = len(labels)

# Create the CNN model
model = Sequential()
model.add(Conv2D(32, (3, 3), activation='relu', input_shape=(image_size[0], image_size[1], 3)))
model.add(MaxPooling2D((2, 2)))
model.add(Conv2D(64, (3, 3), activation='relu'))
model.add(MaxPooling2D((2, 2)))
model.add(Flatten())
model.add(Dense(64, activation='relu'))
model.add(Dense(num_classes, activation='softmax'))
```

Figure 4: CNN architecture.

5. TRAINING THE MODEL

5.1 DATA SPLITTING

The dataset is divided into two parts: 80% for the training set and 20% for the validation set. The training set is utilized to teach the model, while the validation set is employed to assess its performance during training and to minimize the risk of overfitting.

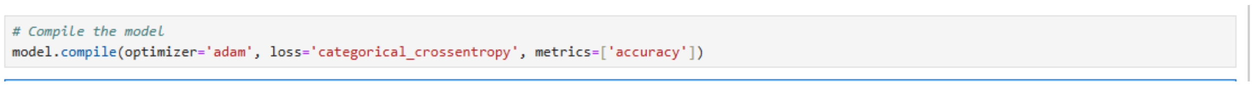
```
# Create an image data generator for data augmentation
data_generator = tf.keras.preprocessing.image.ImageDataGenerator(rescale=1./255, validation_split=0.2)
```

Figure 5: splitting dataset (training – 80% and testing -20%)

5.2 MODEL COMPILATION

To compile the model, the following configurations are used:

- **Optimizer**: The Adam optimizer is chosen for its efficiency in performing gradient descent. It adapts the learning rate during training, making it suitable for models with large datasets and complex architectures.
- **Loss Function**: Categorical Crossentropy is used as the loss function since the task is a multi-class classification problem.
- **Metric**: Accuracy serves as the evaluation metric to track the model's performance on the training and validation datasets.

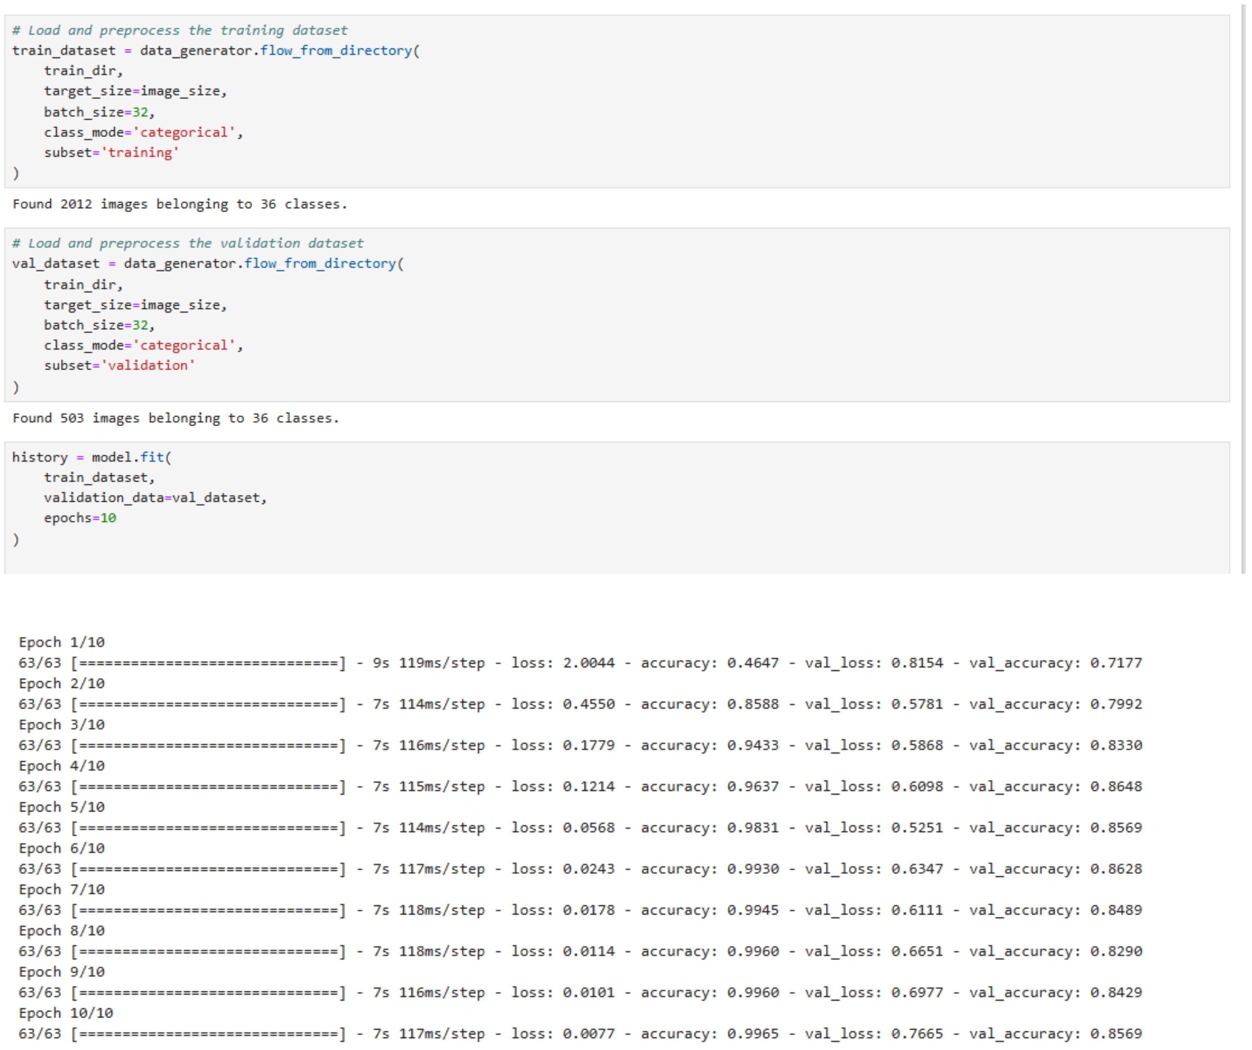


```
# Compile the model
model.compile(optimizer='adam', loss='categorical_crossentropy', metrics=['accuracy'])
```

Figure 6: Model compilation

5.3 TRAINING

The model undergoes training for 10 epochs with a batch size of thirty-two. At the end of each epoch, the model's performance is assessed on the validation set to monitor progress and identify any signs of overfitting.



```
# Load and preprocess the training dataset
train_dataset = data_generator.flow_from_directory(
    train_dir,
    target_size=image_size,
    batch_size=32,
    class_mode='categorical',
    subset='training'
)
Found 2012 images belonging to 36 classes.

# Load and preprocess the validation dataset
val_dataset = data_generator.flow_from_directory(
    train_dir,
    target_size=image_size,
    batch_size=32,
    class_mode='categorical',
    subset='validation'
)
Found 503 images belonging to 36 classes.

history = model.fit(
    train_dataset,
    validation_data=val_dataset,
    epochs=10
)
```

```
Epoch 1/10

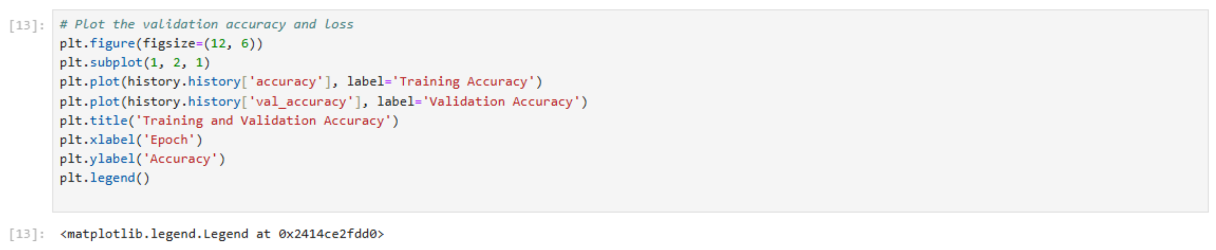
```

Figure 7: Training the model (epoch= 10)

6. EVALUATION

6.1 PERFORMANCE METRICS

Once training is complete, the model's performance is assessed using accuracy. The accuracy for both the training and validation sets is plotted to visualize the model's learning progress, which aids in determining if the model is overfitting or underfitting.



```
[13]: # Plot the validation accuracy and loss
      plt.figure(figsize=(12, 6))
      plt.subplot(1, 2, 1)
      plt.plot(history.history['accuracy'], label='Training Accuracy')
      plt.plot(history.history['val_accuracy'], label='Validation Accuracy')
      plt.title('Training and Validation Accuracy')
      plt.xlabel('Epoch')
      plt.ylabel('Accuracy')
      plt.legend()

[13]: <matplotlib.legend.Legend at 0x2414ce2fdd0>
```

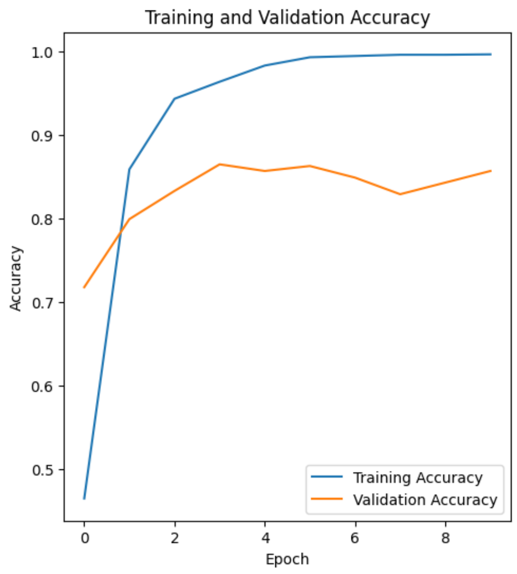


Figure 8: Model training and validation accuracy.

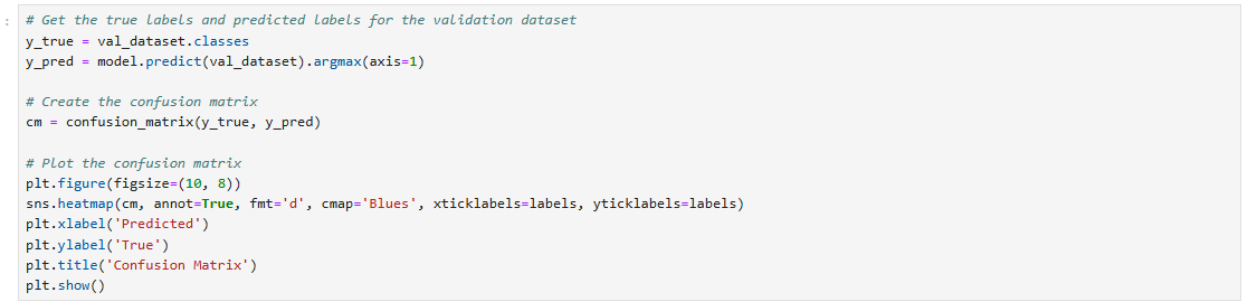
6.2 CONFUSION MATRIX

A confusion matrix is generated to show the model’s performance across all thirty-six classes. It highlights areas where the model struggles, such as confusing similar-looking gestures.



```
# Get the true labels and predicted labels for the validation dataset
y_true = val_dataset.classes
y_pred = model.predict(val_dataset).argmax(axis=1)

# Create the confusion matrix
cm = confusion_matrix(y_true, y_pred)

# Plot the confusion matrix
plt.figure(figsize=(10, 8))
sns.heatmap(cm, annot=True, fmt='d', cmap='Blues', xticklabels=labels, yticklabels=labels)
plt.xlabel('Predicted')
plt.ylabel('True')
plt.title('Confusion Matrix')
plt.show()
```

```
16/16 [==============================] - 1s 65ms/step
```

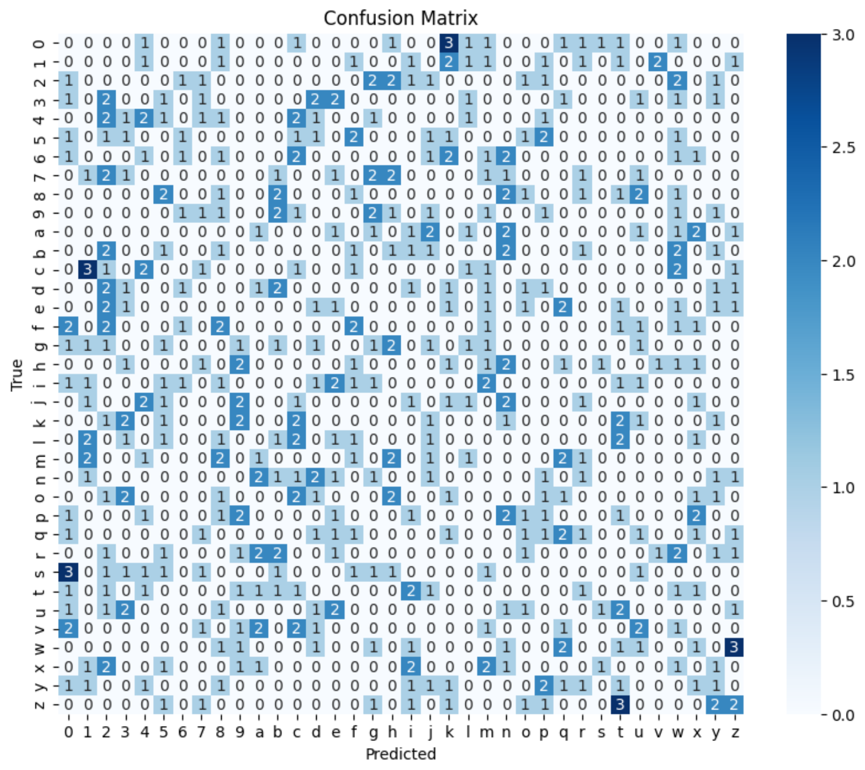


Figure 9: Confusion matrix.

6.3 UNDERSTANDING THE USER INPUT MECHANISM

THE USER INPUT WORKFLOW

The input process involves two key stages: prompting the user for input and processing the input to generate predictions.

STEP 1: PROMPTING THE USER

When the system is ready to accept input, it prompts the user to enter a label. This prompt is displayed on the screen, instructing the user to either provide a sign label or choose a special exit option.

STEP 2: MANAGING INVALID INPUT

If the user enters an invalid label (e.g., anything other than a valid letter, number, or "*"), the system provides feedback and prompts the user again. This is to ensure that the input is valid and corresponds to a recognized sign.

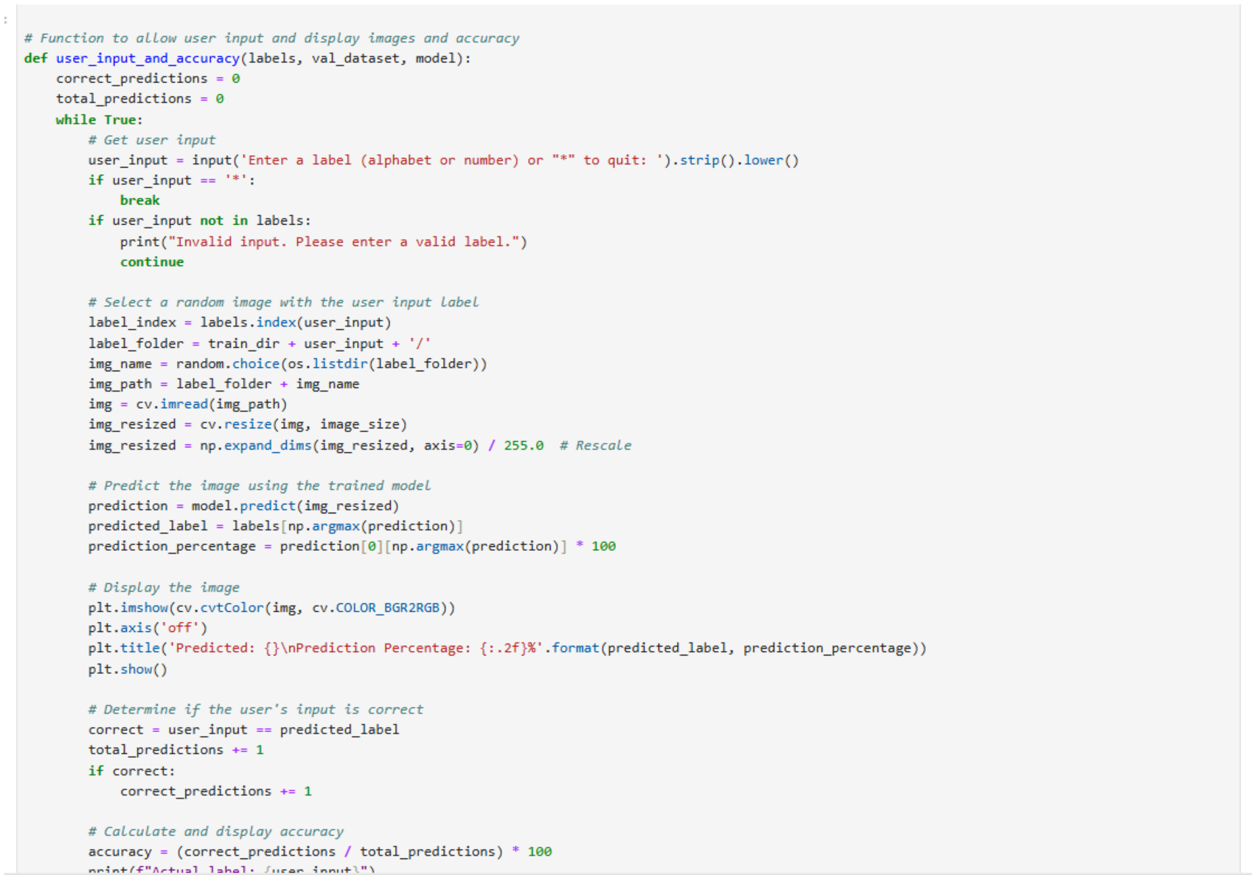
This step ensures that only appropriate inputs are processed, preventing the system from trying to predict signs based on invalid data.

STEP 3: PROCESSING THE INPUT

Once the user enters a valid sign label (e.g., “a” or “3”), the system processes the input and triggers the prediction model. The model will then attempt to match the input sign label (which is associated with a specific image or gesture in the dataset) to a predicted sign label.

STEP 4: EXIT OPTION

If the user enters the exit option (e.g., "*"), the system will terminate the input session, and the user will be taken back to the main menu or end the interaction.



```python
# Function to allow user input and display images and accuracy
def user_input_and_accuracy(labels, val_dataset, model):
    correct_predictions = 0
    total_predictions = 0
    while True:
        # Get user input
        user_input = input('Enter a label (alphabet or number) or "*" to quit: ').strip().lower()
        if user_input == '*':
            break
        if user_input not in labels:
            print("Invalid input. Please enter a valid label.")
            continue

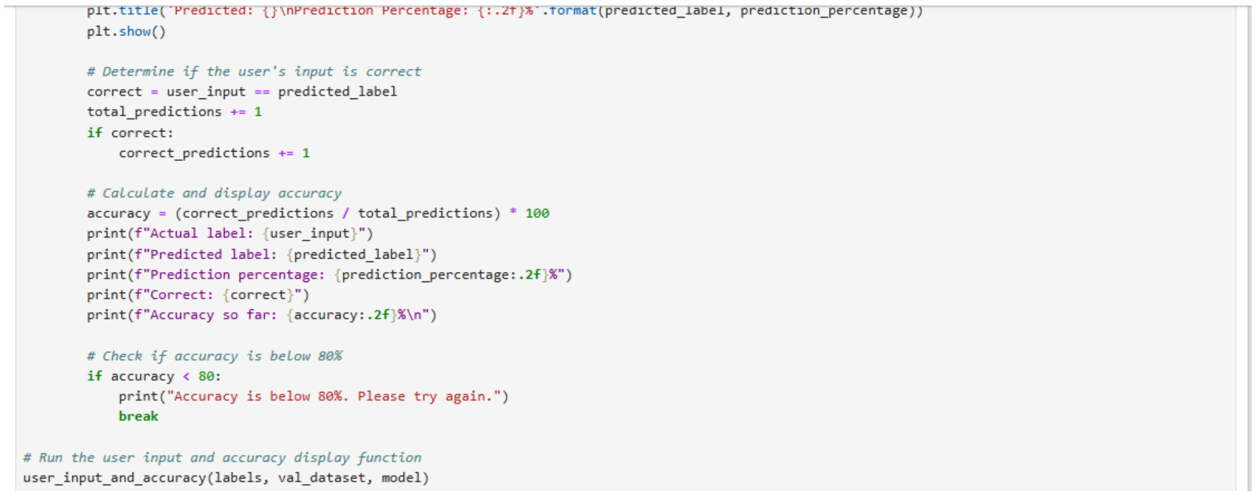
        # Select a random image with the user input label
        label_index = labels.index(user_input)
        label_folder = train_dir + user_input + '/'
        img_name = random.choice(os.listdir(label_folder))
        img_path = label_folder + img_name
        img = cv.imread(img_path)
        img_resized = cv.resize(img, image_size)
        img_resized = np.expand_dims(img_resized, axis=0) / 255.0  # Rescale

        # Predict the image using the trained model
        prediction = model.predict(img_resized)
        predicted_label = labels[np.argmax(prediction)]
        prediction_percentage = prediction[0][np.argmax(prediction)] * 100

        # Display the image
        plt.imshow(cv.cvtColor(img, cv.COLOR_BGR2RGB))
        plt.axis('off')
        plt.title('Predicted: {}\nPrediction Percentage: {:.2f}%'.format(predicted_label, prediction_percentage))
        plt.show()

        # Determine if the user's input is correct
        correct = user_input == predicted_label
        total_predictions += 1
        if correct:
            correct_predictions += 1

        # Calculate and display accuracy
        accuracy = (correct_predictions / total_predictions) * 100
```



```python
        plt.title('Predicted: {}\nPrediction Percentage: {:.2f}%'.format(predicted_label, prediction_percentage))
        plt.show()

        # Determine if the user's input is correct
        correct = user_input == predicted_label
        total_predictions += 1
        if correct:
            correct_predictions += 1

        # Calculate and display accuracy
        accuracy = (correct_predictions / total_predictions) * 100
```

```python
        print(f"Actual label: {user_input}")
        print(f"Predicted label: {predicted_label}")
        print(f"Prediction percentage: {prediction_percentage:.2f}%")
        print(f"Correct: {correct}")
        print(f"Accuracy so far: {accuracy:.2f}%\n")

        # Check if accuracy is below 80%
        if accuracy < 80:
            print("Accuracy is below 80%. Please try again.")
            break

# Run the user input and accuracy display function
user_input_and_accuracy(labels, val_dataset, model)
```

Figure 10: Instruction to print the output (based on user input)

6.4 RESULT OR ACCURACY OF THE MODEL

The model achieved high accuracy in recognizing sign language gestures, demonstrating its ability to correctly predict hand signs corresponding to letters and numbers. Accuracy was tracked during training and validation, ensuring the model could generalize to new data without overfitting. The use of Convolutional Neural Networks (CNNs) allowed the model to learn key features from images, such as shapes and edges, which are crucial for sign language recognition.

7. DISCUSSION

7.1 STRENGTHS

- **High Accuracy**: The model achieved impressive performance on both training and validation data.
- **Automated Feature Extraction**: CNNs eliminated the need for manual feature engineering, learning patterns directly from raw images.
- **Robustness**: Data augmentation enhanced the model's ability to generalize to new data.

7.2 CHALLENGES

❖ Misclassifications: Gestures with overlapping visual features led to some errors.

❖ Dataset Limitations: A small dataset may restrict the model's ability to generalize to unseen data or complex gestures.

6.3 FUTURE DIRECTIONS

- **Dataset Expansion**: Adding more samples and classes to improve diversity and generalization.
- **Real-time Recognition**: Integrating the model into a real-time system using webcams or mobile devices.
- **Regional Variations**: Incorporating gestures from different sign languages for broader applicability.

8. CONCLUSION

This project effectively showcased the use of Convolutional Neural Networks (CNNs) to recognize sign language gestures. By automating feature extraction and classification, the system attained high accuracy and reliability. With continued advancements, such systems have the potential to improve communication for individuals with hearing and speech impairments, fostering greater inclusivity and accessibility.
